

Everybody is always telling you
how big you are. Your mother
says, "Look at your clothes! You're
popping out of them."

Your father says, "Yes, you
certainly are big now."

You look in the mirror and
wonder, "Why do they all say
I'm so big? How big is big?"

An elephant is big. He is the biggest animal in the zoo. If you go for a ride on an elephant, the ground looks very far away. As you sit there, high up on the back of the big elephant, he seems to be the biggest thing in all the world.

Is there anything bigger than an elephant?

Most trees are much taller than the biggest elephant. Even if the elephant lifts his trunk way up, he can't reach the top of a tall tree. It would take many elephants, standing one on top of the other, to reach the top of the tallest tree.

A tree is very big. Is anything bigger than a tree?

A skyscraper is much bigger than a tree. A tall tree doesn't look very big next to a skyscraper. If you went up to the top of the skyscraper and looked down, the biggest tree would look like a toy tree.

A skyscraper is tall. It is taller than the tallest tree in the world. But is there something bigger than a skyscraper?

A mountain is bigger than a skyscraper. This is how the biggest building in the world would look next to the highest mountain in the world.

Twenty-five skyscrapers, piled one on top of another, would be as high as that mountain. Is anything bigger than the biggest mountain?

The moon is bigger than the biggest mountain. This is how big the mountain would look next to the moon. The huge mountain, which is bigger than a skyscraper, bigger than a tree, bigger than an elephant, is not nearly as big as the moon.

The moon, which looks as if it could hide behind a chimney, seems small only because it is so far away.

The moon is very, very big.
Is anything bigger than the moon?

The earth that we live on is bigger than the moon. It would take you four times as long to travel around the earth as around the moon.

The earth is huge, but is the huge earth the biggest thing of all?

No. Every clear morning you look
out of the window and see something
much bigger than the earth. Far, far
off in the sky, the huge shining sun
is much bigger than the earth.
Is there anything still bigger than
the sun?

Yes. Some faraway stars that
twinkle in the sky are hundreds
of times bigger than the sun.

The stars are the biggest things
we know.

So many things are bigger than
you are. Why do people say you are
so big?

You are smaller than a star,
smaller than the sun,
smaller than the moon,
smaller than the mountain,
smaller than a skyscraper,
smaller than a tree,
smaller than an elephant.

How small are you?

How small is small?

A puppy is smaller than you are.
A puppy is small enough to be quite
comfortable sniffing around under
a dining room table. People's legs
look very high to a puppy.

A puppy is small. But is there
something smaller than a puppy?

A mouse is smaller than a puppy.
A little pet mouse is so small that
he can sit in your hand.
Is anything smaller than a mouse?

A flea is smaller than a mouse.
To a flea, a mouse is very big. The
flea has to take a long walk to go
from one end of the mouse
to the other.

Fleas are so small that a barrel
will hold more fleas than there
are people living in the whole United
States. But fleas are not too small
to learn to act in circuses. They
are trained to pull tiny wagons,
wheelbarrows, and cannon. Special
magnifying glasses are needed to
make the tiny fleas look big enough
for people to see them act.

Fleas are small. But there are
things even smaller than fleas.

A mite is smaller than
a flea.

A flea is tiny, but he looks very big
to the little mite on his back. This
little animal can ride on a flea's
back as easily as you can ride on an
elephant. This is how a mite riding
flea-back would look under a very
strong magnifying glass. A mite is
so small that a blade of grass is a
broad highway to him.

A mite is very small. Is there
anything still smaller than a mite?

A mite is very small indeed. But there are tiny water animals, called protozoa, that are smaller still. Oceans and lakes, ponds and mud puddles, all have some of these tiny water animals in them.

A drop of water from a flower bowl has dozens of kinds of protozoa scurrying around in it. If you look carefully, you can see the larger ones as tiny specks. This picture shows them hundreds of times bigger than they are.

Protozoa are very small, but are they the smallest things of all?

No. Protozoa are tiny animals, but the water plants which protozoa eat are much tinier. These plants, called algae,* are the green grass of the water world. The picture shows what some of the different kinds of algae look like under a powerful microscope. Most algae are so small that you cannot see them even as tiny specks. But millions and millions of tiny algae together make the pale green color of the water in a fish bowl.

Is anything smaller than these algae?

*Pronounced al-jee.

Yes. There are things even smaller than algae—things millions of times smaller. These are the things of which everything and everybody is made. They are called atoms.

This is how an atom would look next to one of the tiniest algae.

Imagine how small atoms are. Your hand is made of more atoms than there are leaves on all the trees, fishes in all the seas, people in all the world.

Can anything possibly be smaller than an atom?

Yes. Each atom is made of things that are smaller still. These things are called electrons, protons, and neutrons. No one has ever seen them clearly, but we think they look like this:

You can't see them even with the most powerful microscope. But in every flash of lightning that rips across the sky you see millions and billions and trillions of electrons streaking from one cloud to another or from a cloud to the earth.

Electrons, protons, neutrons—these are the smallest things we know in all the world.

So many things smaller and
smaller. So many things bigger and
still bigger. Where do you belong?

You belong right in the middle,
between an electron and a star.

A star is many, many times bigger
than you are. But you are just about
as many, many times bigger than
an electron.

You are just the right size.

How Big and How Small

THE BIG THINGS

You are about 4 feet tall.

An elephant is about 11 feet tall.

A very tall oak tree is about 140 feet tall.

The tallest building in the world, the Empire State Building, is 1250 feet, or about a quarter of a mile, high.

The tallest mountain in the world, Mt. Everest, is over 29,000 feet, or about five and a half miles high.

The moon is about 2000 miles in diameter (measuring from one side through the middle to the other side).

The earth is about 8000 miles in diameter (from the North Pole to the South Pole through the center).

The sun is about 860,000 miles in diameter.

Some stars are more than 400 times bigger than the sun.

THE SMALL THINGS

You are about 4 feet tall.

Puppies come in many sizes, but the puppy in this book is about one foot tall.

A mouse is about 4 inches long from the tip of his nose to the end of his tail.

Fifteen ordinary fleas lined up in a row would measure one inch.

There are many sizes of mites, but seventy-five of the smaller kind in a row would measure one inch.

Three hundred medium-sized protozoa in a line would measure one inch.

A thousand medium-sized algae side by side would measure one inch.

Some atoms are much bigger than others, but one hundred million of the biggest atoms in a row would measure one inch.

Electrons, protons, and neutrons are about a million times smaller than atoms.
